

# Keeping Track of Free Blocks

- Method 1: *Implicit list* using length—links all blocks

Assignment Project Exam Help

- Method 2: *Explicit pointers* using pointers

- Method 3: *Segregated free list*

- Different free lists for different size classes

- Method 4: *Blocks sorted by size*

- Can use a balanced tree (e.g. Red-Black tree) with pointers within each free block, and the length used as a key

# Segregated List (Seglist) Allocators

- Each *size class* of blocks has its own free list

- Often have separate classes for each small size
- For larger sizes: One class for each two-power size

# Seglist Allocator

- Given an array of free lists, each one for some size class
- To allocate a block of size  $n$ :
  - Search appropriate free list for block of size  $m \geq n$
  - If an appropriate block is found:
    - Split block  $a$  into two blocks:  $a$  and  $a - n$  (optional)
  - If no block is found
  - Repeat until block is found
- If no block is found:
  - Request additional heap memory from OS (using `sbrk()`)
  - Allocate block of  $n$  bytes from this new memory
  - Place remainder as a single free block in largest size class.

# Seglist Allocator (cont.)

## ■ To free a block:

- Coalesce and place on appropriate list (optional)

## ■ Advantages of seglist allocators

- Higher throughp
  - log time for <https://eduassistpro.github.io/>
- Better memory utilization
  - First-fit search of segregated fr ates a best-fit search of entire heap.
  - Extreme case: Giving each block its own size class is equivalent to best-fit.
